

SPECIFICATION

1

2

To all whom it may concern:

3

Be it known that Jeffrey Robison, Steven Chipman, and Craig C. Smith, citizens

4

of the United States of America, have invented and new and useful invention entitled

5

BANDED VALVE PLUG HEAD of which the following comprises a complete

6

specification.

BANDED VALVE PLUG HEAD

Background of the Invention

Field of the Invention. This invention relates to industrial valves. More specifically, this invention relates to valve plug heads for industrial valves. Still more specifically, this invention relates to valve plugs which employ dissimilar materials and devices for attaching valve plug heads to valve plug stems.

Description of Related Art. Valves, valve plugs and associated components are well known in the art. Valve plug heads are generally positioned within the valve in the middle of the flow stream to control the volume of flow that is allowed to pass through the valve. By varying the position of the plug head relative to the valve seat control of the flow volume is achieved. In sum, the valve plug head is used within a valve to divert and restrict flow. Plug heads are subjected to fluid forces, chemical attack, thermal stresses, impact from particulates and debris, as well as the forces used to attach it to the plug stem. Additionally, the plug head is subjected to seat loading forces should it contact the valve seat.

The typical valve head is attached to a plug stem, which in turn is connected to an actuating device. This actuating device, which is typically positioned outside the internal portion of the valve, is controlled to move the plug stem, thereby changing the position of the plug head and controlling the volume of flow passing through the valve. Thus the attachment between the plug stem and the plug head is inside the valve, exposed to the flow stream, while the actuator and the attachment between the actuator and the plug stem are outside the valve and are not exposed to the flow stream. Typically, between the internal portion of the valve stem, which is exposed to the flow stream, and the external

1 portion of the valve stem, which is connected to the actuator, is a smooth cylindrical
2 section that is used as a sealing surface. Valve packing is placed around and against this
3 cylindrical section, permitting in and out movement of the plug stem, without flow
4 stream leakage out of the valve. The plug stem is therefore subjected to axial forces as
5 the actuator moves it, mounting forces relating to the actuator attachment, and the long
6 cylindrical section is subjected to bending forces. The plug head and the plug stem
7 perform distinctly different purposes and are subjected to very different forces. The plug
8 head, sitting in the middle of the flow stream, diverts and/or restricts flow, and is
9 subjected to fluid and seat loading forces and to forces related to attaching the plug head
10 to the plug stem. While the plug stem, adapted to be moved by an actuating device
11 provides a sealing surface and is subject to axial and bending forces. In industrial, high
12 volume, high flow rate valves these forces on plug stems and plug heads are typically
13 significant contributors to valve failure.

14 Traditionally, valve plug heads are either composed of one monolithic material or
15 make use of more than one material. Plug heads employing more than one type of
16 material have particular advantages, in particular better erosion and corrosion resistance,
17 improved shock absorption, working life, and thermal expansion qualities. However,
18 typically the use of a plurality of material types has been limited by the ability to
19 effectively join the materials together economically and without creating stress points
20 that limit the life of the plug head. The most common current methods of fixing
21 dissimilar materials together in a valve plug are taper fitting or interference fitting, both
22 of which employ a retaining ring that is fixed around the plug head.

1 Taper fittings have been shown to subject the plug head to undesirable stresses,
2 contribute to thermal expansion problems and are not practical to repair. The typical
3 taper fitting design requires a mating of two conical surfaces, one on the plug head, and
4 the other on the retaining ring. Since neither the plug head nor the retaining ring can be
5 manufactured to completely ideal cone shapes, the plug and seat may not mate perfectly,
6 therefore loading between the two when mated may not be uniform. Moreover, the force
7 of the retaining ring on the plug head, that holds the plug head in place, is located close to
8 the edge of the plug head and is generally perpendicular to the angle of the conical
9 surface. The location and angle of this force are undesirable because they introduce
10 tensile forces into the portion of the plug head that bears the force. Often the desired plug
11 head material may demonstrate weak tensile strength, therefore, introducing additional
12 tensile forces may either limit the selection of plug head materials or, if desired plug head
13 materials are used, may tend to break off the edge of the plug head, separating the plug
14 head from the plug stem and causing valve failure. Also, as the retaining ring wears
15 away, through corrosion and erosion, the shape of the contact area can change, typically
16 moving closer to the edge of the plug head. This contact area change tends to concentrate
17 forces on the edge of the plug head and increases the likelihood that the edge of the plug
18 head will fracture, thereby also causing the plug head to separate from the plug stem.
19 The stresses induced with the taper fit are difficult to quantify and, therefore, can detract
20 from a valve plug's performance. The stresses are difficult to predict because the plug
21 head is held in place by the retaining ring and the retaining ring is attached to the plug
22 stem via welding. Variables in the welding process such as weld shrinkage, inter-pass
23 temperature, amperage of weld, inert gas environment, number of passes between

1 welding pauses, the amount of initial burn in, as well as other related welding factors can
2 change the amount of stress in the plug head.

3 As noted above, typical prior taper fit designs attach the taper fit ring to the plug
4 stem via welding. This approach results in the retaining ring and the plug stem
5 essentially becoming permanently joined into one component. If the plug head wears
6 away or breaks and the plug stem is still usable, the typical taper fit design does not lend
7 itself to achieving the proper concentricity between the plug head and the plug stem after
8 the plug head has been replaced. When taper fit valve plugs are originally manufactured,
9 the plug stem is the last portion of the plug to be machined. This is done so that it can be
10 machined concentric with the plug head. When a taper fit valve plug is repaired, the plug
11 stem has already been machined, so it is not possible to make adjustments in the plug
12 stem to ensure concentricity with the plug head. Also, if the plug head is misaligned,
13 when the taper fit ring is welded in place, adjustments cannot be made for concentricity
14 without cutting the taper fit ring off again. Since the welding of the taper fit ring involves
15 difficult to predict shrinkage and distortion of the taper fit ring, it is not generally possible
16 to assure that the plug head will be properly concentric with the plug stem after the taper
17 fit ring is welded in place. For these reasons, it is the current industry practice to discard
18 taper fit valve plugs when the plug head has broken or worn away, rather than to attempt
19 to repair them.

20 Additionally, with many plug head material classes, the coefficient of thermal
21 expansion is less than that of many taper fit ring material classes. Generally, in
22 assembling the part, the taper fit ring is fit tightly around the ceramic and the taper fit ring
23 is welded to the plug stem. At elevated operating temperatures, the taper fit ring

1 increases in size more than the plug head, and the plug head becomes somewhat loose in
2 the taper fit ring, thereby leading to early failure of the fit in operating conditions.

3 Interference fittings typically require a bulkier retaining ring, contributing to the
4 load on the plug head; a complex difficult procedure to replace plug heads; and are
5 generally limited in their service temperature ranges. An interference fit achieves more
6 uniform loading of the plug head than does the taper fit. However, the typical
7 interference fit uses a one-piece retaining ring that not only holds the plug head but also
8 attaches the plug head / retaining ring assembly to the plug stem and which must have
9 sufficient material to allow for the wear due to erosion and corrosion without causing the
10 plug head to separate from the plug stem. This requirement results in a bulkier retaining
11 ring than is actually required to hold the plug head in place, and thereby contributes to an
12 additional load on the plug head. This additional load introduces tensile stresses, which
13 tend to contribute to plug head breaking and separation, thereby resulting in valve failure.
14 The shape of the interference fit rings makes it difficult to assess loads and to determine
15 the stresses on the plug head resulting from the portion of the ring that does not contact
16 the plug head. Even using complex finite element analysis (FEA) models, a variety of
17 assumptions are required to determine the value and direction of these stresses.

18 While acceptable concentricity between the plug head and the plug stem can be
19 achieved with prior interference fit designs, nevertheless, the task of replacing the plug
20 head is quite complex. To replace the plug head, first the interference fit ring must be
21 cut, separating the plug head and ring assembly from the plug stem. This is usually
22 performed on a lathe or mill. After cutting the interference fit ring / plug assembly, if the
23 ring is to be used again, it is necessary to separate the ring from the plug head. Since, the

1 ring and plug head are interference fit together, separating them can be exceptionally
2 difficult. With certain combinations of plug head and interference fit ring materials, they
3 can be separated by placing the assembly in an industrial oven and heating. If the
4 coefficient of thermal expansion of the retaining ring is sufficiently higher than the plug
5 head, the retaining ring will expand more quickly and the interference fit will be negated
6 as a space forms between the two surfaces. This approach is somewhat destructive and
7 requires that the interference-fit ring be carefully checked before reuse. Also, this
8 heating method only works with certain combinations of materials. For example, if the
9 plug head has a larger coefficient of thermal expansion than the interference fit ring, as
10 when the interference fit ring is made from titanium or zirconium and the plug head is
11 made from MgO ZrO₂ ceramic, then heating increases rather than decreases the amount
12 of interference between the parts. Moreover, even when it may work, the plug head
13 replacement process requires specialized manufacturing facilities, that are generally
14 unavailable to users in remote locations. Therefore, replacing plug heads for valve plugs
15 is not a typical industry practice for certain combinations of materials or user locations.

16 Another problem with interference fittings is that service temperature ranges are
17 limited because of differential thermal expansion between the plug head and ring
18 materials. Typically, the first step in interference fit plug design is to determine how
19 much interference between the plug head and the ring is required at operating
20 temperature in the valve to ensure that the plug head is held securely in place. Next, a
21 determination is made as to how much interference would exist at ambient temperatures.
22 In many cases, the class of plug head material has a lower coefficient of thermal
23 expansion than does the interference fit ring. Therefore, the amount of interference is

1 U.S. Patent No. 4,771,803 describes a ball cock with a sinter ceramic valve seat
2 and valve ball for a fluid, which contains abrasive particles.

3 U.S. Patent No. 4,791,953 describes a regulator and shut-off valve for use in a
4 corrosive media.

5 U.S. Patent No. 4,815,704 describes a ball valve that comprises a pressure tight
6 housing, a valve ball, an operating shaft, and a valve seat.

7 U.S. Patent Nos. 4,911,403 and 5,007,614 describes a pressure responsive two-
8 way shut-off valve for use with high-pressure gas cylinders, which is adapted to
9 automatically retain residual pressure in the cylinder.

10 U.S. Patent No. 5,353,832 describes a ball cock for fluids carrying abrasive
11 materials that has its inlet passage terminating with a smaller cross section than the mouth
12 of a ball passage which, in turn, has a smaller cross section than the mouth of the outlet
13 passage aligned therewith.

14 U.S. Patent No. 5,386,967 describes a coupler for use in a rotary ball valve having
15 a spherical ball with a passageway therethrough controlling the flow of fluid through the
16 valve.

17 U.S. Patent No. 5,605,172 describes a fluid control valve and method for
18 subjecting a liquid to a controlled pressure drop.

19 U.S. Patent No. 5,618,026 describes a hybrid rotary control valve for use on
20 existing rotary concentric control valve, or ball valve platforms.

21 **Summary of the Invention**

22 It is desirable to provide a valve plug design that uses a plug head band and a
23 retaining ring to attach the valve plug head to its valve plug stem, and to thereby provide

1 a means of employing different materials for the plug head and the plug stem, where the
2 different materials are selected specifically to address the different function of the plug
3 head and the plug stem. This type of plug design is particularly desirable for use in flow
4 streams that are erosive or corrosive in nature, because plug heads in these kinds of
5 streams typically suffer material loss due to the erosion and/or corrosion. After a certain
6 amount of material is lost, the plug head becomes ineffective at controlling the flow
7 within the valve and needs to be replaced. Often the plug head wears out before other
8 valve components. Therefore, minimizing the occurrences when the plug head fails and
9 must be replaced is very desirable in improving the life cycle and efficiency of the valve.

10 Moreover, it is desirable to provide a design for plug heads and plug stems that
11 permits the use of plug head materials, which are highly corrosion and erosion resistant
12 and permits the use of plug stem materials, which can be easily machined, have good
13 tensile strength, are reasonably ductile, and can be polished to a very smooth surface.
14 Therefore, it is also desirable to provide a design for plug heads and plug stems that
15 reliably joins highly dissimilar materials without inducing undesired stresses or thermal
16 shock failures. It is also desirable to provide a valve plug head and stem design which
17 can be serviced and repaired at the user site.

18 Therefore, it is the general object of this invention to provide a valve plug design
19 that permits the use of different materials for the plug head and the plug stem.

20 It is a further object of this invention to provide a valve plug that uses a corrosion
21 resistant material for the plug head.

22 It is another object of this invention to provide a valve plug that uses an erosion
23 resistant material for the plug head.

1 A further object of this invention is to provide a valve plug design that permits the
2 valve plug head to be repaired or replaced in the field with a minimum of special
3 manufacturing equipment and procedures.

4 Another object of this invention is to provide a valve plug that uses a plug stem
5 material that is easily machined.

6 A still further object of this invention is to provide a valve plug that uses a plug
7 stem material that has good tensile strength.

8 A further object of this invention is to provide a valve plug that uses a plug stem
9 material that is reasonably ductile.

10 It is a further object of this invention to provide a valve plug that uses a plug stem
11 material that can be polished to a smooth surface.

12 It is another object of this invention to provide a valve plug design that minimizes
13 plug head stresses.

14 Another object of this invention is to provide a valve plug design that minimizes
15 thermal stresses.

16 A further object of this invention is to provide a valve plug design compatible
17 with post-weld heat treatments to provide stress relief at weld zones.

18 A still further object of this invention is to provide a valve plug that uses a
19 retaining ring to attach the valve plug head to the valve plug stem.

20 It is a further object of this invention to provide a valve plug having a band placed
21 around the valve plug head, using an interference fit, where the band has contours that
22 match up to contours in the retaining ring.

1 It is another object of this invention to provide a valve plug design that imposes a
2 uniform stress on the plug head.

3 It is a still further object of this invention to provide a valve plug design that
4 permits the use of one alloy for the plug head band and a different alloy for the band
5 retainer and a third alloy for the plug stem.

6 An additional object of this invention is to provide a valve plug design that lowers
7 the overall cost of materials.

8 A further object of this invention is to provide a valve plug design that simplifies
9 the task of replacing worn out plug heads.

10 Another object of this invention is to provide a valve plug having a shock
11 absorbing barrier around the plug head band, permitting the plug head to “give” and
12 adjust its alignment in response to trying to close the valve on a piece of scale or debris in
13 the flow.

14 An additional object of this invention is to provide a valve plug having a shock
15 absorbing barrier around the plug head band, permitting the plug head to “give” and
16 adjust its alignment in response to trying to close the valve in the valve seat to shut off
17 the flow through the valve.

18 It is a further object of this invention to provide a valve plug having designed in
19 compliance which allows the plug head to “self align” with the seat, thereby making
20 critical alignment during manufacturing and servicing less critical.

21 It is a still further object of this invention to provide a valve plug having a
22 compliant joint, whereby the head seats optimally in the valve seat without the creation of
23 excessive forces or stresses.

It is another object of this invention to provide a valve plug where the compliant joint is provided with a “smart” actuator to allow the actuator to adapt to wear or erosion of the valve head. The actuator being provided with a control means such that the actuator will close until the force in the compliance reaches some predetermined level, rather than controlling the position of the head open-loop.

Another object of this invention is to provide a valve plug having a compliant joint that allows the head to self-center on the seat.

Still another object of this invention is to provide a valve plug having a compliant joint that reduces the stresses created by dynamic loading of the head, as when debris in the flow field strikes the head or when the head strikes the seat.

Another object of this invention is to provide a joint which allows placement of sensors to permit monitoring of plug head conditions.

A still further object of this invention is to provide a valve plug designed so as to allow interchangeable heads with a variety of valve stem designs.

It is another object of this invention to provide a valve plug having reduced manufacturing costs because of relaxation of head-seating tolerances.

It is a still further object of this invention to provide a valve plug where the retention band temperature expansion is matched to the head temperature expansion and is independent of the stem temperature expansion.

A further object of this invention is to provide a valve plug having a thermally-insulating barrier around the plug head band.

It is a further object of this invention to provide a valve plug providing improved uniformity and a broad contact between the plug head and the plug head band.

1 It is a still further object of this invention to provide a valve plug using less
2 material.

3 It is another object of this invention to provide a valve plug that requires no
4 welding to attach the plug head to the plug stem, for certain applications.

5 Another object of this invention is to provide a valve plug that can use selected
6 pin materials to attach the retainer while using an interference fit to hold the band retainer
7 tightly to the plug stem.

8 A still further object of this invention is to provide a valve plug that joins together
9 materials that are not easily welded, brazed, coated or glued together because of material
10 properties or service conditions.

11 It is another object of this invention to provide a valve plug design that reduces
12 assembly stresses and makes it easier to predict and control stresses before, during and
13 after the intended service of the plug.

14 These and other objects of this invention are intended to be covered by this
15 disclosure and will be readily apparent to those of ordinary skill in the art upon review of
16 the following drawings, detailed description, claims and abstract or may be learned from
17 the practice of the invention. The objects and other advantages of this invention may be
18 realized and attained by means of the instrumentalities and combinations particularly
19 pointed out in the appended claims. As will be realized, this invention is capable of
20 different embodiments, including but not limited to different materials and dimensions,
21 and are capable of modification in various important aspects without departing from the
22 invention. Accordingly, the drawings and descriptions should be regarded as illustrative
23 in nature and not as restrictive.

1 To achieve the foregoing and other objectives, and in accordance with the
2 purposes of the present invention includes a plug head, a plug stem, a band retainer, a
3 plug band, one or more retention pins and a plug stem base, which when assembled
4 provides the improved valve plug head / stem of this invention.

5 **Brief Description of the Drawings**

6 The accompanying drawings incorporated in and forming a part of the
7 specification, illustrate a preferred embodiment of the present invention. Some although
8 not all, alternative embodiments are described in the following description. In the
9 drawings:

10 Figure 1 depicts a section view of the preferred plug head mounted in the
11 preferred plug stem of this invention.

12 Figure 2 depicts a representative system drawing of the preferred plug stem of this
13 invention in a valve assembly.

14 Figure 3 depicts a section view of an alternative plug head mounted in the plug
15 stem, this embodiment has additional compliance structure provided.

16 Figure 4 depicts a section view of a second alternative embodiment of the
17 invention, having a different fastener mechanism and having multiple embedded sensors
18 for the communication of stress information.

19 Reference is now made in detail to the present preferred embodiment of the
20 invention an example of which is illustrated in the accompanying drawings.

21 **Detailed Description of the Preferred Embodiment of the Invention**

22 This invention is a valve plug design that uses a plug head band and a retaining
23 ring to attach valve plug heads to valve plug stems. In particular, this invention is

1 adapted to address the requirements of valves used in industries, such as mining,
 2 chemical processing, and oil and gas refining, where the flow is abrasive and/or corrosive
 3 and which may contain substantial quantities of sediment, debris or scale. Valves in
 4 certain erosive and/or corrosive flow streams encounter a significant amount of sediment,
 5 debris or scale which comes through the pipe line. Often erosive flow streams such as
 6 slurries form a scale on the internal walls of pipes, tanks and vessels through which the
 7 slurry flows. This scale can become hard and refractory. From time to time as the scale
 8 breaks away from the inside walls, it joins with the flow stream and travels through the
 9 subject valves. This invention is adapted to pass this scale and other debris while
 10 avoiding much of the stresses caused by the valve plug attempting to close on scale or
 11 debris.

12 Moreover, this invention provides plug heads and stems being made of dissimilar
 13 materials having different properties that optimize the performance of the plug head, the
 14 plug stem and the fastening band.

15 Also, this invention is adapted to ease the process of repair and replacement of
 16 valve plug components, permitting maintenance to be accomplished in the field without
 17 requiring specialized manufacturing equipment or highly skilled personnel.

18 Referring now to the figures and in particular to Figure 1, a section view of the
 19 preferred plug head and plug stem of the present invention is illustrated. The preferred
 20 valve plug 100 is shown having a plug head 101 held in a plug stem base 103 which in
 21 turn is mounted on the plug stem 102. The preferred plug stem base 103 has a cavity 110
 22 for receiving the plug head 101. Within the walls of the cavity 110 of the plug stem base
 23 103 is a recess 105 for receiving the plug head band 104. Also, provided in the plug stem

1 base 103 are a plurality of bolt holes 111a,b adapted to receive a plurality of bolts 106a,b.
2 The plug head 101 is held in the plug stem base 103 by a plug head band 104 which
3 provides a broad interference fit between the plug head 101 and the recess 105 in the plug
4 stem base cavity 110. A band retainer 108 is fitted over the plug head band 104 and is
5 tightly held in place by the plurality of bolts 106a,b. In the preferred embodiment of the
6 invention, the bolts 106a,b are fixed in place by nuts 107a,b. Alternatively, the band
7 retainer 108 can be held in place to the plug stem base 103 by (pins, screws, welds,
8 brazing, clamps or the equivalent.) A shoulder 109 of the plug stem base 103 provides a
9 good fit to the valve stem support (or shaft support) (see 206 of figure 2).

10 An inset 112 detail view of the cross-section of the plug head band 104 is shown
11 to provide additional detail of the preferred shape of the band 104. This preferred band
12 104 has a first side 113 for contacting the plug head 101 and a second side 114 opposite
13 the first side 113, sized to fit tightly to the inside of the recess 105 of the plug stem base
14 103 cavity 110. Preferably, the first side 113 is significantly larger in height 115 than
15 the second side 114. This plug band 104 shape serves both to enhance the surface contact
16 area of the first side 113 and to provide shock absorbing capabilities, thereby providing
17 stress relief to the plug head 101 during use.

18 The preferred plug head 101 is composed of structural ceramics because of its
19 resistance to wear and degradation in flow streams that are erosive (having fine-grit
20 particles) and corrosive (due to the chemical composition of the flow). Structural
21 ceramics are a class of materials that includes, but is not limited to silicon carbide, silicon
22 nitride, aluminum oxide, zirconium oxide, tungsten carbide, whisker-reinforced blends of
23 ceramics, two-phase ceramics and the like. Alternative materials which may be

1 substituted for structural ceramics for the plug head 101, include, but are not necessarily
2 limited to, cermets, which are compounds that are combinations of ceramics and metals,
3 cast iron, silicon iron, white iron, heat treated martensitic steels (such as 440 or 416 grade
4 steel), CrCoFe alloys (such as stellite #3, stellite #6, and stellite #12), or other metals.
5 Alternative materials with similar properties can be substituted without departing from
6 the concept of this invention.

7 The preferred plug stem 102, plug stem base 103 and band retainer 108 is
8 composed of materials selected for ease of machining to a smooth surface, having good
9 tensile strength, reasonable ductility and cost effectiveness. Included within this class of
10 materials are titanium and its alloys, zirconium and its alloys, niobium and its alloys,
11 titanium-niobium alloys, alloy steels, carbon steels, iron-base superalloys, stainless steels,
12 nickel and its alloys, nickel-base superalloys, copper based alloys, cobalt alloys, cobalt-
13 base superalloys, aluminum and its alloys, magnesium alloys, tantalum and the like.
14 Alternative materials with similar properties can be substituted without departing from
15 the concept of this invention.

16 The preferred plug head band 104 is composed of metal alloys, including but not
17 limited to titanium and its alloys, zirconium and its alloys, niobium and its alloys,
18 titanium-niobium alloys, alloy steels, carbon steels, iron-base superalloys, stainless
19 steels, nickel and its alloys, nickel-base superalloys, copper based alloys, cobalt alloys,
20 cobalt-base superalloys, aluminum and its alloys, magnesium alloys, tantalum and metals
21 of similar properties. Alternative materials with similar properties can be substituted
22 without departing from the concept of this invention.

Figure 4 shows the section view of a second alternative embodiment of the invention, having a different fastener mechanism and having multiple embedded sensors for the communication of stress information. This embodiment 400 has a plug head 401 held in a plug stem base 403 which in turn is mounted on the plug stem 402, as described in detail above is reference to figure 1. The essential differences between this embodiment 400 and that described in reference to figure 1, is a substitute fastening means of fastening the retaining ring 410 to the plug stem base 403. In this embodiment the means of fastening is a weld, braze or the like 411, instead of the bolt or pin mechanism of figure 1. Also, this embodiment 400, has a plurality of vertical compliance devices 407, 408, 409. In this particular embodiment, the preferred vertical compliance devices are a variety of spring devices. Shown here are a parallel washer spring 408, a series-parallel washer spring 407, and a series washer spring 409. Preferably, the same spring type would be used in all compliance locations in the plug stem base 403. The three different types are shown here to demonstrate the variety of spring types available. Alternative, equivalent springs can be substituted without departing from the concept of this invention. Also, provided in this embodiment 400 are alignment-pressure sensors 406a,b. These sensors 406a,b could be positioned in a wide variety of alternative positions at the interface between the plug head 401 and the plug stem base 403, and are shown along the band 404.

The described embodiments, including the various materials specific components and dimensions, are to be considered in all respects only as illustrative and not as restrictive. The invention should not be considered limited to the particular preferred and alternative embodiments, rather the scope of the invention is indicated by the appended

- 1 claims. All changes, modifications and alternatives which come within the meaning and
- 2 range of equivalency of the claims are to be embraced as within their scope.
